			95lb	90-94	95-99	100-104	105-109	110-114	115-119	120-124	125-129	130-134	135-139	140-144	145-149	150-154

Bow poundage can also be show with #

All shaft spines stated above are in lb / #

All wooden shafts are measured over 26" on a spining jig as per the ATA Standards. The values above are only a guidance and could be different depending on your style of shooting, type of thumbing used, etc. BUT it gives you a starting point. The this should help with the dynamic spine of the arrow during flight, this is basically reducing the 'wobble' / flex of the arrow during flight and the loss of energy / forward motion of the arrow.

DISCLAIMERS: Please not shaft diameter will need to be decided by the archer when using this information and could affect the way the arrow flies, as well as the final spine needed. For shaft sizes below 5/16" you may have to go up in spine(s) to achieve the dynamic spine wanted in arrow flight. This table is just a starter guide. All info is based on a parallel shaft, if arrow is tapered or barrelled this will affect the arrow spine. A stiffer arrow shaft will need to be used as a base parallel form to make the tapered or barrelled.

Refer to the Dal's Archery Techincal Page as the above can be affected by what string material is used on your bow, bracing height, etc. all these things affect the spine of arrow you need.
